ABSTRACT

It is shown that there exist OL languages which cannot be generated by deterministic ETOL systems. This solves an open problem posed in Rozenberg (1973).
0. INTRODUCTION

Developmental systems and languages have recently gained considerable attention in both formal language theory and theoretical biology (see, e.g., Lindenmayer (1968), Lindenmayer & Rozenberg (1972), Herman, Lindenmayer & Rozenberg (1973) and their references).

From the biological point of view, developmental systems have provided a useful theoretical framework within which the nature of cellular behavior in development can be discussed, computed and compared. From the formal language theory point of view they have provided us with an alternative to the now standard Chomsky framework (see, e.g., Hopcroft & Ullman, (1969)) for defining languages.

The concept of a tabled OL system was introduced by Rozenberg (1972) to model the role of environment in developmental processes, and it is currently the subject of active research, see, e.g. Rozenberg (1972, 1973) or Ehrenfeucht & Rozenberg (1973). In this paper we are concerned with a kind of tabled OL systems called an extended tabled OL system. We use the abbreviations TOL system for tabled OL system and ETOL system for extended tabled OL system.

An ETOL system has the following components:

(i) A finite set of symbols, $V$, the alphabet.

(ii) A starting string $\omega$, the axiom.

(iii) A finite set of tables of production rules, each of which tells us by what strings in $V^*$ a symbol from $V$ may
be replaced. The set of productions that may be applied to a certain symbol depends on the symbol only. In every step of a derivation all symbols in the string must be simultaneously replaced according to the production rules of one single arbitrarily chosen table of the system.

(iv) A subset $\Sigma$ of the alphabet $V$, the **target alphabet**. The **language of a system** (called an ETO1 language) is the set of all strings over the target alphabet which can be derived from the axiom, possibly including the axiom itself.

An ETO1 system is called **deterministic**, abbreviated as an EDT0L system if each of its tables is such that for each letter in the alphabet $V$ the table provides exactly one string by which the letter can be replaced.

The role of the deterministic restriction in developmental systems is an important aspect of the theory from both the biological and formal language theory points of view. This problem in connection with tabled systems was investigated among others in Rozenberg (1972), Rozenberg (1973) and in Ehrenfeucht & Rozenberg (1973).

In particular it was proved in Rozenberg (1973), that every ETO1 language can be generated by an ETO1 system such that in every table there are no more than two productions provided for each symbol in the alphabet. In the same paper it was left as an open problem whether each ETO1 language can be generated by a deterministic ETO1 system.
In this paper we prove that the solution to the above problem is negative, it means that there is an ETOL language which cannot be generated by any EDTOL system.
I. DEFINITIONS AND EXAMPLES

In this section we introduce all of the necessary terminology and illustrate it by examples. We use conventional formal language theory notation, see e.g. Hopcroft & Ullman (1969), augmented by the following.

(i) If $A$ is a set, then $\#A$ denotes the cardinality of $A$.

(ii) If $x$ is a word over an alphabet $\Sigma$, $x=a_1 \ldots a_p$ for $p \geq 1, a_1, \ldots, a_p \in \Sigma$, then

$$\text{Min}(x) = \{a \in \Sigma : a \text{ occurs in } x\},$$

$|x|$ denotes the length of $x$, and if $1$ is a positive integer then

$$\text{Pref}_1(x) = \begin{cases} a_1 \ldots a_l & \text{if } l \leq p, \\ x & \text{otherwise.} \end{cases}$$

$x^e$ will abbreviate the word $x$ catenated with itself $e$ times.

(iii) $\Lambda$ denotes the empty word.

(iv) $\mathbb{N}$ denotes the set of nonnegative integers and $\mathbb{N}^+ = \mathbb{N} - \{0\}$.

Definition 1. An extended tabled OL system (abbreviated as an ETOL system) is a 4-tuple $G = \langle V, P, \omega, \Sigma \rangle$, where

- $V$ is a finite nonempty set (the alphabet of $G$),
- $\omega$ is an element of $V^+$ (the axiom of $G$),
- $\Sigma$ is a subset of $V$ (the target alphabet of $G$),
- $P$ is a finite nonempty set, each element of which (called a table) is a finite nonempty binary relation included in $\Sigma \times \Sigma^*$.

$P$ satisfies the following (completeness) condition:

for every $P$ in $P$ and for every $a$ in $V$ there exists $\alpha \in V^*$ such
that \(<a, a> is in P.\)

If \(P\) is a table and \(<a, a> \in P\) then \(<a, a> is called a production
and denoted as \(a \rightarrow a.\) We shall write \(a \rightarrow a\) for "\(a \rightarrow a\) is in \(P.\)"

\[\text{Definition 2. Let } G = \langle V, P, w, \Sigma \rangle \text{ be an ETOL system.} \]

I) Let \(x \in V^+, y \in V^*\) where \(x = a_1 \ldots a_p\) for \(a_1, \ldots, a_p \in V.\)

We say that \(x\) \text{ directly derives } y \text{ (in } G), \text{ denoted as } x \rightarrow^G y,
if there exists a table \(P\) in \(P\) such that \(a_1^+ \alpha_1, \ldots, a_p^+ \alpha_p\) for some \(\alpha_1, \ldots, \alpha_p\) such that \(y = \alpha_1 \ldots \alpha_p.\) Also by convention

\[\Lambda \rightarrow A, \quad P\]

II) Let \(x, y \in V^*.\)

We say that \(x\) \text{ derives } y \text{ (in } G), \text{ denoted as } x \rightarrow^* y, \text{ if either } x = y \text{ or there exists a sequence } x_0, \ldots, x_n \text{ of words in } V^*
such that \(x_0 = x, x_n = y \text{ and } x_{i-1} \rightarrow^G x_i \text{ for } 1 \leq i \leq n.\)

III) The \text{ language of } G \text{ or the language generated by } G, \text{ denoted as } L(G), \text{ is defined as follows}

\[L(G) = \{x \in \Sigma^*: x \rightarrow^* x \}.\]

(Whenever \(G\) is understood we write \(x \rightarrow y\) and \(x \rightarrow^* y\) rather
than \(x \rightarrow y\) and \(x \rightarrow^* y\) respectively).

\[\text{Definition 3. Let } G = \langle V, P, w, \Sigma \rangle \text{ be an ETOL system.} \]

I) \(G\) is called a \text{ deterministic ETOL system}, abbreviated as
an \text{ EDTOL system}, if for every \(P\) in \(P\) and every \(a\) in \(V\) there
exists exactly one \(a\) in \(V^*\) such that \(a \rightarrow a.\)
II) G is called a **OL system** if \( V = \Sigma \) and \( P \) contains exactly one table.

**Definition 4.** Let \( \Sigma \) be a finite alphabet and \( L \subseteq \Sigma^* \). L is called a **(deterministic) ETOL language** or a **OL language** if there exists a (deterministic) ETOL system or a OL system \( G \) respectively such that \( L(G) = L \).

By \( F(ETOL) \), \( F(EDTOL) \) and \( F(OL) \) we shall denote the classes of ETOL languages, EDTOL languages and OL languages respectively.

**Example 1.** Let \( G = <\{a, b\}, \{P_1, P_2\}, a, \{a, b\}> \) be an ETOL system where \( P_1 = \{a + a^2, b + b\} \), \( P_2 = \{a + a, a + ab, a + ba, b + b\} \).

\( L(G) = \{x \in \{a, b\}^+: \text{the number of occurrences of the letter } a \text{ in } x \text{ equals } 2^n \text{ for some } n > 0\} \).

(Note that \( G \) is neither an EDTOL nor a OL system).

**Example 2.** Let \( G = <\{a, b\}, \{P\}, a, \{a, b\}> \) be a OL system where \( P = \{a + b, a + a, a + ab, a + aa, b + b\} \). \( L(G) = \{a, b\}^+ \).

Now, following Herman & Rozenberg (1973), we shall define derivations in ETOL systems.

**Definition 5.** Let \( G = <V, P, \omega, \Sigma> \) be an ETOL system. A **derivation** \( D \) in \( G \) is a triple \( <O, f, g> \) where \( O \) is a set of ordered pairs of nonnegative integers (the **occurrences** in \( D \)), \( f \) is a function from \( O \) into \( V \) (\( f(i, j) \) is the **value** of \( D \) at occurrence \( <i, j> \)), and \( g \) is a function from a subset of \( O \) into \( P \cup P \) satisfying the following conditions. There exists a sequence of words \( (x_0, x_1, \ldots , x_s) \) in \( \Sigma^* \) (called the **trace** of \( D \).
and denoted as \( tr(D) \) such that

(i) \( O=\{<i,j>:0\leq i\leq s, 1\leq j\leq |x_i|\} \),

(ii) \( f(i,j) \) is the \( j \)'th symbol in \( x_i \),

(iii) the domain of \( g \) is \( \{<i,j>:0\leq i\leq s, 1\leq j\leq |x_i|\} \), (elements of \( O \) which are not in the domain of \( g \) are called final occurrences),

(iv) for \( 0\leq i\leq s \) there exists a \( P \) in \( \mathcal{P} \) such that for \( 0\leq j\leq |x_i| \), \( g(i,j)=\langle P, f(i,j)\alpha_j \rangle \), where \( f(i,j)\alpha_j \) and \( \alpha_1\alpha_2\ldots\alpha_{|x_i|}=x_{i+1} \).

In such a case \( D \) is said to be a derivation of \( x_s \) from \( x_0 \).

The sequence of tables \( T_1,\ldots,T_s \) such that the first element of \( g(i,j) \) for \( 0\leq i\leq s-1, 0<i\leq j \leq s \) is \( T_{i+1} \) is called the control sequence of \( D \). The sequence \( T_j, T_{j+1},\ldots,T_m \) where \( 1\leq j\leq m \) is called the control sequence from \( x_{j-1} \) to \( x_m \). If \( <i,j> \) is an occurrence in \( D \) then we also say that \( x_i \) contains this occurrence.

The set \( \{ |x_i|:0\leq i\leq s \} \) is called the set of lengths in \( D \) and is denoted by \( Lg(D) \).

**Example 3.** Let \( G \) be the ETOL system from Example 1.

Let \( D_1=<O_1,f_1,q_1> \) where

\( O_1=\{<0,1>,<1,1>,<1,2>,<2,1>,<2,2>,<2,3>,<3,1>,<3,2>,<3,3>,<3,4>,<3,5>\} \),

\( f(0,1)=f(1,1)=f(2,1)=f(2,2)=f(3,2)=f(3,3)=a \),

\( f(1,2)=f(2,3)=f(3,1)=f(3,4)=f(3,5)=b \)

\( g(0,1)=g(2,2)=\langle P_2, a\alpha b \rangle, g(1,1)=\langle P_1, a\alpha a \rangle, g(1,2)=\langle P_1, b\alpha b \rangle, g(2,1)=\langle P_2, a\alpha b \rangle, g(2,3)=\langle P_2, b\alpha b \rangle \)

\( D_1 \) is a derivation of \( ba^2b^2 \) from \( a \). The trace of \( D_1 \) is
a, ab, a^2b, ba^2b^2. The control sequence of D_1 is P_2, P_1, P_2.

\{<3,1>, <3,2>, <3,3>, <3,4>, <3,5>\} is the set of final occurrences.

Given an ETOL system G and a derivation D in G, there is a natural way of representing D by a graph-like structure called the **derivation graph** of D. Although such a representation can be defined formally, we believe that for the purpose of this paper this and other related notions are best explained by examples.

**Example 4.** The derivation in Example 3 is represented by the following derivation graph:

```
  P_2
 /   \
 a   a
 /   \ /   \   \
 a   b P_2 P_2
 /   /   /   |
 a   a P_2
 /       /   |
 b       a   b
```

The occurrence \(<1,2>\) is a **direct ancestor** of the occurrence \(<2,3>\) and is an **ancestor** of the occurrence \(<3,5>\). Thus the occurrence \(<2,3>\) is the **direct descendant** of the occurrence \(<1,2>\), and the occurrence \(<3,5>\) is a **descendant** of the occurrence \(<1,2>\). The trace of this derivation is \(x_0, x_1, x_2, x_3\) and in fact we shall also say that \(<3,5>\) is a **descendant** of \(<1,2>\) in \(x_3\), and so on.

We say that, for example, the occurrence \(<1,2>\) **contributes two occurrences** (\(<2,1>\) and \(<2,2>\)) on the level \(x_2\) (or simply on the level 2). In fact in this case we can say that the occurrence \(<1,2>\) **contributes on the level** \(x_2\) two occurrences in one step.

The number of occurrences contributed on the "final" level (\(x_3\))
by an occurrence $<i,j>$ is called the weight of $<i,j>$. If the weight of a given occurrence in a derivation $D$ is equal to 0, then this occurrence is called D-improductive (and otherwise it is called D-productive). If $x_i$ is a word in the trace of a derivation $D$ and we 'erase' all improductive occurrences of letters in $x_i$ then the resulting word is denoted by $\text{Prod}(x_i)$. We define $Lg(\text{Prod}(D))$ to be the set $\{|\text{Prod}(x_i)|:0<i<s\}$.

Note that derivations and derivation graphs are in one-to-one correspondence in the sense that, given a derivation $D$ one can construct the unique derivation graph $M$ which represents $D$, and conversely, given a derivation graph $M$, one can uniquely construct the unique derivation $D$ which is represented by $M$.

By looking at derivation graphs it is easy to see that each occurrence $<i,j>$ in a derivation determines a unique $<i,j>$-subderivation from $f(i,j)$ into a substring of $x_s$ (where $x_0, \ldots, x_s$ is the trace of the given derivation). We denote such a subderivation by $D(i,j)$. If we are interested in the derivation 'leading' from $x_0$ to $x_e$ only (where $0 \leq e \leq s$) then we denote it by $D^e$. (Thus $D^s=D$). For example if $e=2$ and $D$ is a derivation from Example 4 then $D^2$ is represented by the following derivation graph

```
  a
 /\  \\
 a b  P_2
/  \
/   \\
 a b  P_1
```

If we consider an EDTOL system then, obviously, the first element of the trace of a given derivation $D$ together with the control sequence of $D$ uniquely determine the derivation.
In such a case if \( \text{tr}(D) = x_0, \ldots, x_s \) then we write \( x_0 = \omega = [0], x_1 = \omega = [1], \ldots, x_s = \omega = [s] \), where the EDTOL system under consideration has the axiom \( \omega \).
II. PRELIMINARY RESULTS

In this section we shall prove a number of preliminary results needed for the proof of the main theorem (Theorem 1).

For the rest of this paper let $L = \{x \epsilon \{0,1\}^*: |x|=2^n \text{ for some } n \geq 0\}$.

**Lemma 1.** For every $n$ in $\mathbb{N}^+$ there exists a word $x(n)$ in $L$ such that $|x(n)|=2^n$ and $x(n)$ does not contain any two non-overlapping occurrences of the same word of length $3n$.

**Proof.**

Let $n \epsilon \mathbb{N}^+$ and let $y(n)$ be the following word:

$$y(n) = 0^n a_1 0^n a_2 \ldots 0^n a_2^n 0^n$$

where $a_1, \ldots , a_2^n$ is a listing (without repetitions) of the set of all words of length $n$.

Now if we let

$$x(n) = \text{Pref}_{2^n}(y(n))$$

then Lemma 1 obviously holds.

Through a series of lemmata (lemmata 2 through 13) we shall show that the assumption that $L=H(G)$ for some EDTOL system $G$ leads to a contradiction (Lemma 13). In fact we shall show that each EDTOL system which generates $x(n)$ for $n$ "large enough" must also generate a word whose length is not a power of $2$.

Thus let us assume that $G=\langle V, P, \omega, \Sigma \rangle$ is an EDTOL system such that $L(G)=L$. Let $\#V=k, |\omega|=r, m=\max\{ |\alpha| : a+\alpha \text{ for some } a \in V \}$. $P \epsilon P$
Let \( n \) be a "large enough" positive integer (how large \( n \) should be is defined in the proofs of lemmata 7 and 14) and let us consider the word \( x(n) \) defined in the proof of Lemma 1. Let \( D = \langle O, f, q \rangle \) be a derivation of \( x(n) \) in \( G \) and \( \omega = \omega_0, \omega_1, \ldots, \omega_s \) be the trace of \( D \).

Let \( \langle i, j \rangle \) be a \( D \)-productive occurrence in \( D \).

If \( \langle i, j \rangle \) is not final and the last word in the trace of \( D(i, j) \) is of length greater than or equal to \( 3n \), then \( \langle i, j \rangle \) is called a large occurrence (in \( D \)). Otherwise it is called a small occurrence (in \( D \)).

It follows directly from the definitions that

**Lemma 2.** Each descendant of a small occurrence is a small occurrence.

**Lemma 3.** Let \( \langle i, j \rangle, \langle i, j' \rangle \) be in \( O \). If \( f(i, j) = f(i, j') \) then \( \langle i, j \rangle \) is a small occurrence if, and only if, \( \langle i, j' \rangle \) is a small occurrence. (Thus we can talk about big and small letters on a given level \( i \)).

**Lemma 4.** Let \( \langle i, j \rangle \) be a big occurrence in \( D \). If \( j \neq j' \) and \( \langle i, j' \rangle \) is in \( O \), then \( f(i, j) \neq f(i, j') \).

**Proof.**

If \( \langle i, j \rangle \) and \( \langle i, j' \rangle \) are in \( O \) and \( \langle i, j \rangle \) is a big occurrence then (Lemma 3) so is \( \langle i, j' \rangle \). But \( G \) is deterministic and so if \( j \neq j' \) and \( f(i, j) = f(i, j') \), then \( x(n) \) would contain two non-overlapping occurrences of the same subword of length \( 3n \); a contradiction.
Thus as a direct consequence of Lemma 4 we have the following result.

**Lemma 5.** For every \( i \in \mathbb{N}^+ \) there are at most \( k \) big occurrences of the form \( \langle i, j \rangle \).

Now, let us estimate the length of \( \text{Prod}(\omega^{[1]}) \) for a given \( l \leq s \).

Let \( U(l) \) be an arbitrary (but fixed) subset of \( \{0, 1, \ldots, l\} \) such that for every \( p \in \text{Lg}(\text{Prod}(D^l)) \), \( U(l) \) contains exactly one element \( v \) in \( \{0, 1, \ldots, l\} \) such that \( |\text{Prod}(\omega^{[v]})| = p \). Let \( u_1 = \#U(l) \).

**Lemma 6.** For \( l \leq s \), \( |\text{Prod}(\omega^{[1]})| \leq r \cdot 3 \cdot n + k \cdot m \cdot 3 \cdot n \cdot u_1 + k \).

**Proof.**

(i) The axiom \( \omega \) contains not more than \( r \) small occurrences and each of them contributes not more than \( 3n \) small occurrences on a given level \( l \). Hence the component \( r \cdot 3 \cdot n \).

(ii) If \( p \in U(l) \) then (see Lemma 5) \( \omega^{[p]} \) contains at most \( k \) big occurrences each of which can introduce in one step not more than \( m \) small occurrences. Each of these can contribute not more than \( 3 \cdot n \) small occurrences on the given level \( l \). But \( \#U(l) = u_1 \). Hence the component \( k \cdot m \cdot 3 \cdot n \cdot u_1 \).

(iii) From Lemma 5 it follows that \( \omega^{[1]} \) contains at most \( k \) big occurrences. Hence the component \( k \).

**Lemma 7.** \( u_s > \frac{2^n}{C \cdot n} \) for some positive integer.
Proof.

From Lemma 6 it follows that

$$2^n = |\text{Prod}(\omega[s])| < r \cdot 3 \cdot n + k \cdot m \cdot 3 \cdot n \cdot u_s + k$$

Hence

$$u_s > \frac{2^n - (k + r \cdot 3 \cdot n)}{k \cdot m \cdot 3 \cdot n} = \frac{2^n}{k \cdot m \cdot 3 \cdot n} - \left( \frac{1}{m \cdot 3 \cdot n} + \frac{r}{k \cdot m} \right) > \frac{2^n}{c \cdot n}$$

for some (large enough) positive integer $C$, and $n$ "large enough"

so that

$$\frac{2^n}{k \cdot m \cdot 3 \cdot n} - \left( \frac{1}{m \cdot 3 \cdot n} + \frac{r}{k \cdot m} \right) > 0.$$

Now for $0 < l \leq s$ let us introduce the following notation:

$B(\omega[l])$ denotes the number of big occurrences in $\omega[l]$,

$S(\omega[l])$ denotes the number of small occurrences in $\omega[l]$,

$I(\omega[l])$ denotes the number of D-improductive occurrences in $\omega[l]$,

Using this notation let us introduce the following definition.

Two elements $l_1$, $l_2$ of $U(s)$ are called compatible if:

(i) $\text{Min}(\omega[l_1]) = \text{Min}(\omega[l_2])$,

(ii) $B(\omega[l_1]) = B(\omega[l_2])$,

(iii) $S(\omega[l_1]) = S(\omega[l_2])$,

(iv) $I(\omega[l_1]) = I(\omega[l_2])$,

(v) If $a \in S(\omega[l_1]) = S(\omega[l_2])$ then $a$ contributes the same number of occurrences in $\omega[s]$ from level $l_1$ and level $l_2$.

(We also say that $l_1$, $l_2$ are $<\text{Min}(\omega[l_1]), B(\omega[l_1]), S(\omega[l_1]), I(\omega[l_1])>$-compatible.)
If \( \overline{U} \subseteq U(s) \), then \( U \) is called compatible if for some subsets \( A_1, A_2, A_3, A_4 \) of \( V \), \( \overline{U} \) is the set of all pairwise \( <A_1, A_2, A_3, A_4> \)-compatible elements from \( U(s) \). (We also say that \( A_1, A_2, A_3, A_4 \)-compatible).

**Lemma 8.** If \( \overline{U} \) is a compatible subset of \( U(s) \) then
\[
\# \overline{U} \geq \frac{2^n}{C_1 \cdot n^{k+1} \cdot 2^k \cdot 3^k}
\]
where \( C_1 \) is a positive integer constant.

**Proof.**

Let \( \overline{U} \) be an \( <A_1, A_2, A_3, A_4> \)-compatible subset of \( U(s) \).

(i) From Lemma 7 it follows that \( u_s \geq \frac{2^n}{C \cdot n} \) for some positive integer \( C \).

(ii) There are no more than \( 2^k \) choices for \( A_1 \).

(iii) For the given \( A_1 \) there are no more than \( 3^k \) choices of \( A_2, A_3, A_4 \) out of \( A_1 \).

(iv) For the given choice of \( A_3 \) one can choose at most \( (3n)^k \) different lengths of contributions into level \( \omega_s \).

(v) Thus \( \# U \geq \frac{2^n}{C \cdot n \cdot 2^k \cdot 3^k \cdot (3n)^k} = \frac{2^n}{C_1 \cdot n^{k+1} \cdot 2^k \cdot 3^k} \)
where \( C_1 = C \cdot 3^k \).

So let \( \overline{U} \) be a compatible subset of \( U(s) \), say \( \overline{U} = \{p_1, \ldots, p_t\} \), where \( p_1, \ldots, p_t \) are in ascending order.

Let \( p_i, p_{i+1} \in \overline{U} \). We say that a small occurrence in \( \omega_{p_{i+1}} \) is new if its ancestor in \( \omega_{p_i} \) is a big occurrence.
Lemma 9. If \( p_i, p_{i+1} \in U \) then \( \omega_{p_{i+1}} \) contains at least one new occurrence.

Proof.

Let us assume to the contrary, that \( \omega_{p_{i+1}} \) does not contain any new occurrence. We shall prove (by induction on the weight of a small occurrence) that under this assumption each small occurrence in \( \omega_{p_i} \) has exactly one descendant in \( \omega_{p_{i+1}} \).

(i) Let \( e \) be the maximal weight for a small occurrence in \( \omega_{p_i} \) and let \( \omega_{p_i} \) contain \( v \) letters with this weight. But \( \omega_{p_{i+1}} \) does not contain any new occurrence and so if a small letter in \( \omega_{p_i} \) with weight \( e \) has more than one descendant in \( \omega_{p_{i+1}} \), then each of them has a weight smaller than \( e \). Hence (remembering that a letter with weight \( e \) can only be introduced by a letter with weight \( e \)) \( \omega_{p_{i+1}} \) contains at most \( v-1 \) letters with weight \( e \) which contradicts the compatibility of \( U \).

(ii) Let us assume that the claim is true for all small letters in \( \omega_{p_i} \) with weight equal to or greater than \( w \).

(iii) Let \( a \) be a small letter in \( \omega_{p_i} \) with weight \( w-1 \) (where \( w-1 > 1 \)). By the inductive assumption no small letter in \( \omega_{p_i} \) with weight equal to or greater than \( w \) can introduce a letter with weight \( (w-1) \) in \( \omega_{p_{i+1}} \). Hence if the letter \( a \) has more than one descendant in \( \omega_{p_{i+1}} \) then the number of small
letters with weight w-1 in \( \omega_p \) and in \( \omega_{p_i+1} \) is different, which contradicts the compatibility of \( \overline{U} \).

So we have proved that (under our assumption) each small occurrence in \( \omega_p \) has exactly one descendant in \( \omega_{p_i+1} \). But then

\[
|\text{Prod}(\omega[p_i])| = |\text{Prod}(\omega[p_{i+1}])|
\]

which contradicts the fact that \( \overline{U} \subseteq U(s) \).

Thus \( \omega_{p_{i+1}} \) must contain at least one new small occurrence, and consequently the result holds.

Out of all possible choices of \( \overline{U} \) (first the choice of \( U(s) \) and then of \( \overline{U} \) out of \( U(s) \)) let us choose one which will give us a minimal value for \( p_{i+1} - p_i \) for some \( p_{i+1}, p_i \) in \( \overline{U} \) (where \( \overline{U} = \{p_1, \ldots, p_t\} \)). Let \( p_{i_0}, p_{i_0+1} \) be such a minimal choice of consecutive "levels" from the so chosen \( \overline{U} \).

**Lemma 10.** \( p_{i_0+1} - p_{i_0} \leq C_2 n^{k+1} \) for some positive integer \( C_2 \).

**Proof.**

As \( |x(n)| = 2^n, \# \text{Lg}(D) \leq 2^n \).

From Lemma 8 it follows that \( \# U \geq \frac{2^n}{C_1 \cdot n^{k+1} \cdot 2^k \cdot 3^k} \).

Thus \( p_{i_0+1} - p_{i_0} \leq \frac{2^n \cdot C_1 \cdot n^{k+1} \cdot 2^k \cdot 3^k}{2^n} = C_2 n^{k+1} \), where \( C_2 = C_1 \cdot 2^k \cdot 3^k \).
Lemma 11. The number of new occurrences of small letters in \( \omega_{p_i + 1} \) (denoted as \( \text{New}(p_i + 1) \)) satisfies the inequality

\[
\text{New}(p_i + 1) \leq C_3 \cdot n^{k+2}
\]

for some positive integer \( C_3 \).

Proof.

(i) From Lemma 10 it follows that

\[
p_i + 1 - p_i \leq C_2 \cdot n^{k+1}
\]

for some positive integer \( C_2 \).

(ii) According to Lemma 5 there are at most \( k \) big occurrences on any "level" in \( D \).

(iii) Each big letter in one step of a derivation can introduce not more than \( m \) small occurrences.

(iv) Each small occurrence can contribute at most \( 3 \cdot n \) occurrences on level \( \omega_{p_i + 1} \).

(v) Altogether

\[
\text{New}(p_i + 1) \leq C_2 \cdot n^{k+1} \cdot k \cdot m \cdot 3 \cdot n = C_3 \cdot n^{k+2}
\]

where \( C_3 = C_2 \cdot k \cdot m \cdot 3 \).

Let \( T_1, T_2, \ldots, T_s \) be the control sequence of \( D \).

Let \( D(p_i, p_{i+1}) \) be the derivation defined by the axiom \( \omega \) and the control sequence \( T_1, T_2, \ldots, T_{p_i - 1}, T_{p_i}, T_{p_{i+1}}, \ldots, T_s \).

Let \( \omega = z_0, z_1, \ldots, z_h \) be the trace of \( D(p_i, p_{i+1}) \).
Lemma 12. \( z_h \) is in \( L(G) \) and \( |x(n)| - |z_h| \leq C_4 \cdot n^{k+3} \), where \( C_4 \) is a positive integer constant.

**Proof.**

\( z_h \) is in \( L(G) \) because \( G \) is deterministic and \( p_i, p_{i+1} \) are in the same compatible set \( \overline{U} \).

(i) \( |x(n)| = |\omega_s| = x_1 + x_2 \), where \( x_1 \) is the number of occurrences in \( \omega_s \) contributed (in \( D \)) by small occurrences in \( \omega_{p_i} \), and \( x_2 \) is the number of occurrences in \( \omega_s \) contributed (in \( D \)) by big occurrences in \( \omega_{p_i} \).

(ii) \( |z_h| = y_1 + y_2 \), where \( y_1 \) is the number of occurrences in \( z_h \) contributed in \( D(p_i, p_{i+1}) \) by small occurrences in \( z_{p_{i-1}} = \omega_{p_{i-1}} \), and \( y_2 \) is the number of occurrences in \( z_h \) contributed in \( D(p_i, p_{i+1}) \) by big occurrences in \( z_{h} = \omega_{p_i} \). (The expressions "big occurrences" and "small occurrences" refer here to the classification of occurrences in \( z_{p_i} = \omega_{p_i} \) in \( D \) and not in \( D(p_i, p_{i+1}) \)).

(iii) Because \( p_i \) and \( p_{i+1} \) are compatible, each letter \( a \) which is small in both \( \omega_{p_i} \) and \( \omega_{p_{i+1}} \) contributes the same number of occurrences in \( \omega_s \) independently of whether it contributes from \( \omega_{p_i} \) or from \( \omega_{p_{i+1}} \). But the control sequence from \( \omega_{p_{i+1}} \) to \( \omega_s \) in \( D \) is identical to the control sequence from \( z_{p_i} \) to \( z_h \)
in $D(p_i, p_{i+1})$. Hence $X_1 = Y_1$.

(iv) $X_2 = X_{21} + X_{22}$, where

$X_{21}$ is the number of occurrences in $w_s$ contributed (in $D$) by
big occurrences in $w_{p_{i+1}}$, and

$X_{22}$ is the number of occurrences in $w_s$ contributed (in $D$) by
new occurrences in $w_{p_{i+1}}$.

(v) Because $p_i$ and $p_{i+1}$ are compatible, $B(w_{p_i} = z_{p_i}) = B(w_{p_{i+1}})$.

But the control sequence from $w_{p_i}$ to $w_s$ (in $D$) is identical
to the control sequence from $z_{p_i}$ to $z_h$ in $D(p_i, p_{i+1})$. Thus
$X_{21} = Y_2$.

(vi) Thus $|x(n)| - |z_h| \leq 3 \cdot n \cdot X_{22}$, and so from Lemma 11 it
follows that $|x(n)| - |z_h| \leq 3 \cdot n \cdot C_3 \cdot n^{k+2}$, where $C_3$ is the constant
defined in Lemma 11. Letting $C_4 = 3C_3$ we have the result.

**Lemma 13.** $L(G)$ contains a word (in fact $z_h$) whose length
is not a power of 2.

**Proof.**

From the proof of Lemma 12 it follows that $|z_h| < |x(n)| = 2^n$
and from Lemma 13 it follows that

$$|z_h| \geq |x(n)| - C_4 \cdot n^{k+3}.$$ 

Choosing $n$ large enough we combine these two observations to give

$$2^{n-1} < |z_h| < 2^n.$$
III. THE MAIN RESULT.

Theorem 1. There exists a 0L language which cannot be generated by a EDTOL system.

Proof.

Let \( L \) be the language defined in the last section. As the 0L system \( \langle \{0,1\}, P, 0, (0,1) \rangle \), where \( P \) consists of the following productions:

\[
\begin{align*}
  0 & \Rightarrow 00, 0 \Rightarrow 01, 0 \Rightarrow 10, 0 \Rightarrow 11, \\
  1 & \Rightarrow 00, 1 \Rightarrow 01, 1 \Rightarrow 10, 1 \Rightarrow 11,
\end{align*}
\]

generates \( L \), the language \( L \) is a 0L language.

But from lemmata 2 through 13 it follows that \( L \) is not an EDTOL language, and so Theorem 1 holds.

Corollary 1. \( F(EDTOL) \subseteq F(ETOL) \).

Proof.

This follows directly from Theorem 1 and from the fact that by definitions 1, 3 and 4 \( F(0L) \subseteq F(ETOL) \) and \( F(EDTOL) \subseteq F(ETOL) \).
IV. DISCUSSION

The reader may easily observe that the proof of Theorem 1 can be done in almost the same way if one chooses instead of \( L \) another "similar" language, say

\[ K = \{ x \in \{0,1\}^*: |x| = 3^n \text{ for some } n \geq 0 \}. \]

In fact we can generalize the main result as follows. Let \( L \) be an alphabet and \( x \in L^+ \). Let us define \( \mu(x) \) as the minimal positive integer \( n \) such that any two non-overlapping subwords of \( x \) are different.

**Definition 6.** Let \( M \) be a language. \( M \) is called **exponential** if there exists a positive integer \( C \) larger than 1 such that for every \( x_1, x_2 \) in \( M \), if \( |x_1| > |x_2| \) then \( |x_1| > C |x_2| \).

In much the same way as we have proved Theorem 1 one can prove the following result.

**Theorem 2.** If \( M \) is an exponential EDTOL language, then there exists a positive integer constant \( C_M \) such that for every \( x \) in \( M - \{A\} \) we have \( \frac{|x|}{\mu(x)} < C_M \).

**Remark.** We have presented a detailed proof of Theorem 1 rather than the proof of Theorem 2 since this gives a better illustration of the proof technique.
