ABSTRACT

This paper considers the relationship between extended context free normal systems (a nondeterministic version of Tag systems of Post with deletion number equal to 1 and using nonterminals) and ETOL systems. It is demonstrated that the class of languages generated by context free normal systems (denoted \( L(\text{ECFN}) \)) lies strictly between the class of EOL languages (denoted \( L(\text{EOL}) \)) and the class of ETOL languages. Several characterizations of \( L(\text{ECFN}) \) in terms of \( L(\text{EOL}) \) are provided and a number of closure properties of \( L(\text{ECFN}) \) are established.
INTRODUCTION

Normal systems introduced by E. Post in [13] are rewriting systems with (a finite number of) rules of the form \( xP \to Py \) where \( x, y \) are particular words and \( P \) is a variable ranging over the set of all words (over the alphabet of the given system). Post has shown in [13] that even a subclass of the class of normal systems called Tag systems is equivalent to Turing machines. It is shown in [1] that this result remains true even if one considers Tag systems with rules \( xP \to Py \) where the length of \( x \) does not exceed two. In [17] it is shown that this result is not true for Tag systems in which \( x \) is a single letter and this result is strengthened in [2] to arbitrary normal systems with this property. Both H. Wang and S. Cook prove their results by demonstrating that the derivability problem for those systems is decidable.

Then in [10] it is pointed out that the results of H. Wang and S. Cook (and even their proof techniques) are closely related to the theory of L systems and in particular to the work concerning the membership problem for DOL and OL systems (e.g., the paper by P. Doucet [4]). Five years later a more thorough investigation of the relationship between context free normal systems (that is normal systems with rules \( xP \to Py \) where \( x \) is a letter) and L systems is presented in [9]. M. Kudlek proves that the class of languages generated (in the usual way) by context free normal systems using nonterminals, which we abbreviate as ECFN systems, lies between the class of EOL languages and the class of ETOL languages (he also points out that each ECFN system \( G \) has a naturally associated EOL system \( H \) which provides the "backbone" of each derivation in \( G \)). Whether the class of languages generated by ECFN systems (denoted \( L(\text{ECFN}) \)) lies strictly between \( L(\text{EOL}) \) (the class of EOL languages) and \( L(\text{ETOL}) \) (the class of ETOL languages) is left open in [9]. Also the closure of \( L(\text{ECFN}) \) under various basic operations is left open.
In this paper we investigate the precise relationship of $L(\text{ECFN})$ to $L(\text{EOL})$ and $L(\text{ETOL})$. We demonstrate that $L(\text{EOL}) \not\subseteq L(\text{ECFN}) \not\subseteq L(\text{ETOL})$ and provide characterizations of $L(\text{ECFN})$ in terms of $L(\text{EOL})$. We also establish a number of closure properties of $L(\text{ECFN})$.

A normal system rewrites a word while permuting it cyclically from left to right. Hence the operation of cyclic permutation (see, e.g. [15] and [3]) seems particularly suited for the investigation of ECFN systems. As a matter of fact we demonstrate that this operation provides a basic link between ECFN systems and EOL systems. We hope that this paper strengthens the relationship between the classical Tag systems of Post and the more recent EOL systems of Lindenmayer. In particular we show how various known results and techniques of dealing with EOL systems are directly applicable in the analysis of ECFN systems and languages. Also, we think that this paper provides more insight into the topic of cyclic permutations.

We assume the reader to be familiar with basic formal language theory and in particular with EOL systems (see, e.g., [14]).
We mostly use standard language theoretic terminology and notation (see, e.g., [14]). Perhaps only the following points should be noted. For a finite set \( Z \), \( \#Z \) denotes its cardinality; also to simplify the notation we often identify a singleton set with its element. For a word \( x \), \( |x| \) denotes the length of \( x \) and \( \lambda \) denotes the empty word. In this paper we consider only finite nonempty alphabets. Two languages are considered equal if they differ at most by the empty word. For a word \( x \), \( \overline{x} \) denotes the mirror image of \( x \) and for a language \( K \), \( \overline{K} \) denotes the mirror image of \( K \). A homomorphism that maps every letter into a letter is called a coding. It is always assumed that a finite substitution maps each letter into a nonempty set of words. By a gsm mapping we understand the translation of a nondeterministic generalized sequential machine with accepting states.

For the sake of completeness let us recall briefly the notion of an EOL system (see, e.g., [14]). An EOL system is a construct \( G = (\Sigma, h, \omega, \Delta) \) where \( \Sigma \) is an alphabet (the total alphabet of \( G \)), \( \Delta \subset \Sigma \) (the terminal or target alphabet of \( G \)), \( \omega \in \Sigma^* \) (the axiom of \( G \)) and \( h \) is a finite substitution on \( \Sigma^* \). For \( x, y \in \Sigma^* \) we write \( x = y \) whenever \( y \in h(x) \); then \( \mathcal{G} \) denotes the reflexive and the transitive closure of the relation \( = \). The language of \( G \) is defined by \( L(G) = \bigcup_{\mathcal{G}} \{ x \in \Delta^* : \omega = x \} \); we say that \( L(G) \) is an EOL language. If \( \Sigma = \Delta \) then \( G \) is referred to as a OL system and \( L(G) \) as a OL language; in this case \( G \) is specified as \( (\Sigma, h, \omega) \). If for all \( a \in \Sigma \), \( \Delta \notin h(a) \) then we say that \( G \) is a propagating EOL system, abbreviated EPOL system, and that \( L(G) \) is an EPOL language. \( \text{L(EOL)} \) denotes the class of EOL languages.

An ETOL system differs from an EOL system in that it has a finite number of finite substitutions rather than one only. Then a single derivation step (\( = \)) is performed using only one, but arbitrary, finite substitution (in different derivation steps one may use different finite substitutions).
$L(\text{ETOL})$ denotes the class of all ETOL languages.

In the sequel we will often use the following operation.

**Definition.** Let $u, v$ be words. We say that $u$ is a *cyclic conjugate* of $v$ if there exist words $x, y$ such that $u = xy$ and $v = yx$. For a language $K$, the *cyclic permutation* of $K$, denoted $\text{cyc } K$, is defined by $\text{cyc } K = \{ y | y \text{ is a cyclic conjugate of a word in } K \}$. For two languages $K$ and $M$ we say that $K$ is a *cyclic conjugate* of $M$, denoted $K \sim M$, if

1. for every $u \in K$ there exists a $v \in M$ such that $v$ is a cyclic conjugate of $u$, and
2. for every $u \in M$ there exists a $v \in K$ such that $v$ is a cyclic conjugate of $u$. ⊿

It is easy to see that $\sim$ is an equivalence relation.

$\text{cyc } K = \{ xy | xy \in K \}$ and that $K$ is a cyclic conjugate of $M$ if and only if $\text{cyc } K = \text{cyc } M$.

It turns out that, e.g., the classes of regular and context free languages are closed under cyclic permutation (see, e.g., [11] and [15]) but for our paper the following result from [3] is particularly interesting.

**Lemma 1.1** ([3]). $L(\text{ETOL})$ is closed under cyclic permutation. ⊿
II. BASIC DEFINITIONS AND PROPERTIES

In this section we recall from [9] the definition of an extended context free normal system - the basic object of investigation of our paper.

Definition. An extended context free normal system, abbreviated ECFN system, is a construct $G = (\Sigma, h, \omega, \Delta)$ where $\Sigma$ and $\Delta$ are alphabets (the total and the terminal alphabet respectively), $\omega \in \Sigma^*$ (the axiom) and $h$ is a finite substitution on $\Sigma^*$. A direct derivation step (in $G$), denoted by $\Rightarrow$, is defined as follows: if $a \in \Sigma$, $u, v \in \Sigma^*$ and $v \in h(a)$ then $au \Rightarrow uv$. As usual the derivation relation (in $G$), denoted by $\Rightarrow^*$, is defined as the reflexive and transitive closure of $\Rightarrow$. The language of $G$ is defined by $L(G) = \{v \in \Delta^* \mid \omega \Rightarrow^* v\}$; we say that $L(G)$ is an ECFN language. If, for each $a \in \Sigma$, $\Delta \notin h(a)$ then we say that $G$ is an extended propagating context free normal system, abbreviated EPCFN system; $L(G)$ is referred to as an EPCFN language. □

The class of ECFN languages (EPCFN languages respectively) is denoted by $L(\text{ECFN})$ ($L(\text{EPCFN})$ respectively).

Remark. Note that in [9] it is allowed that for a symbol $a$, $h(a)$ is the empty set. However, the reader can easily see that the definition from [9] and our definition are equivalent. □

Thus an EOL system and an ECFN system differ only in the way a direct derivation step is performed. It turns out that the "underlying" OL system of a given ECFN system $G$ plays a very essential role in analysing the language of $G$.

Definition. Let $G = (\Sigma, h, \omega, \Delta)$ be an ECFN system. The underlying OL system of $G$, denoted $U_{OL}(G)$, is the OL system $(\Sigma, h, \omega)$. □

If $u \in \Sigma^*$ and $|u| = n$ then $n$ derivation steps in $G$ starting with $u$ constitute a round (see [17] and [2]) and they yield a word $v \in \Sigma^*$ which
can be obtained from \( u \) in \( U_{OL}(G) \) in one step. Thus every derivation in \( G \) can be considered to consist of a sequence of rounds followed by a sequence of direct derivation steps too short to form a round (see the proof of Lemma 3 in [2] and Theorem 7 in [9]). This is formally expressed by the following basic lemma relating ECFN and EOL systems. (Since this lemma is so basic, for the sake of completeness we give it together with a proof).

**Lemma II.1** ([2], [9]). Let \( G = (\Sigma, h, \omega, \Delta) \) be an ECFN system. Then \( L(G) = \{ v_2u \mid v_2, u \in \Delta^* \text{ and, for some } v_1 \in \Sigma^*, u \in h(v_1) \text{ and } v_1v_2 \in L(U_{OL}(G)) \} \).

**Proof.**
Let \( x \in L(G) \).

If \( x \in L(U_{OL}(G)) \) then obviously we can write \( x \) in the form \( v_2u \) where \( v_2,u \) satisfy the conditions from the statement of the lemma.

If \( x \notin L(U_{OL}(G)) \) then let \( \omega_0 = \omega, \omega_1, \ldots, \omega_n = x \) be a derivation of \( x \) in \( G \) and let \( m < n \) be the largest index such that \( \omega_m \in L(U_{OL}(G)) \). Let \( \omega_m = v_1v_2 \) where \( |v_1| = n - m \). Then clearly \( x = v_2u \) where \( u \in h(v_1) \).

Consequently
\[
L(G) \subseteq \{ v_2u \mid v_2, u \in \Delta^* \text{ and, for some } v_1 \in \Sigma^*, u \in h(v_1) \text{ and } v_1v_2 \in L(U_{OL}(G)) \}.
\]

On the other hand, the reverse inclusion is obvious (one derives \( v_2u \) from \( v_1v_2 \) in \( |v_1| \) steps).

Hence the lemma holds. \( \Box \)

It turns out (see [9]) that each EOL language is also an ECFN language, a fact very useful in our further considerations.

**Lemma II.2** ([9]). \( L(EOL) \subseteq L(ECFN) \).

**Proof.**
Let \( K \in L(EOL) \) and let \( G = (\Sigma, h, \omega, \Delta) \) be an EOL system generating \( K \) (it is well known, see, e.g., [14], that we may assume that \( G \) is propagating). Let \( \overline{\Sigma} = \{ \overline{a} \mid a \in \Sigma \} \) and let \( G_1 = (\Sigma \cup \overline{\Sigma}, h_1, \overline{\omega}, \Delta) \) be the ECFN system where \( h_1(a) = \{ \overline{x} \mid x \in h(a) \} \) and \( h_1(\overline{a}) = \{ a \} \) for all \( a \in \Sigma \) (for a word \( y \), \( \overline{y} \) results from \( y \) by replacing each occurrence of each letter \( a \) in \( y \) by \( \overline{a} \)).
By Lemma II.1,
\[ L(G_1) = \{ v_2 u \mid v_2, u \in \Delta^* \text{ and, for some } v_1 \in \Sigma^*, u \in h_1(v_1) \text{ and } v_1 v_2 \in L(U_{OL}(G_1)) \}. \]
The construction of \( G_1 \) implies that, in the above, if \( v_1 v_2 \in L(U_{OL}(G)) \) then either \( v_1 v_2 \in \Sigma^* \) or \( v_1 v_2 \in \Sigma^* \). Suppose that \( v_1 \) and \( v_2 \) are nonempty. Then \( u \in h_1(v_1) \) implies that \( v_2 u \not\in \Sigma^* \) (because \( G \) is propagating). Thus either \( v_2 \) or \( v_1 \) is empty. Consequently \( L(G_1) = L(U_{OL}(G_1)) \cap \Delta^* \). Since by construction of \( G_1 \), \( L(U_{OL}(G_1)) = L(G) \cup \{ x \mid x \in L(G) \} \) we get \( L(G_1) = L(G) \).

Thus \( L(EOL) \subseteq L(ECFN) \). □

We will prove later on that \( L(EOL) \nsubseteq L(ECFN) \).

However it turns out that each ECFN language has a cyclic conjugate in \( L(EOL) \) - a very basic fact in our proofs in the sequel.

**Theorem II.1.** For every ECFN language \( K \) there exists an EOL language \( M \) such that \( K \sim M \).

**Proof.**

Let \( G = (\Sigma, h, \omega, \Delta) \) be an ECFN system such that \( L(G) = K \). Let
\[ M = \{ uv_2 \mid v_2, u \in \Delta^* \text{ and, for some } v_1 \in \Sigma^*, u \in h(v_1) \text{ and } v_1 v_2 \in L(U_{OL}(G)) \}. \]
By Lemma II.1 \( M \) is a cyclic conjugate of \( K \). Also it is easy to see that there exists a gsm mapping \( g \) such that \( g(L(U_{OL}(G))) = M \). Since it is well-known (see, e.g., [14]) that \( L(EOL) \) is closed under gsm mappings, \( M \) is an EOL language.

Thus the theorem holds. □
III. POSITIVE CLOSURE PROPERTIES

In this section we consider positive closure properties of \( L(\text{ECFN}) \), that is we present several operations which applied to elements of \( L(\text{ECFN}) \) yield languages in \( L(\text{ECFN}) \). The results of this section will be very essential in establishing the precise relationship between \( L(\text{ECFN}) \) on the one hand and \( L(\text{EOL}) \) and \( L(\text{ETOL}) \) on the other hand.

We start with the following obvious result.

**Theorem III.1.** \( L(\text{ECFN}) \) is closed under union.

**Proof.**

Obvious. □

In analysing ECFN systems the following extension of the operation of cyclic permutation will be quite useful.

**Definition.** Let \( \Delta \) be an alphabet, \( K \subseteq \Delta^* \) and \( f \) be a coding on \( \Delta^* \). The \( f\)-cyclic permutation of \( K \) is defined by \( ayc_f K = \{ f(u) \mid u, v \in K \} \).

**Lemma III.1.** Let \( G = (\Sigma, h, \omega, \Delta) \) be an EOL system and let \( f \) be a coding on \( \Delta^* \). Then \( ayc_f L(G) \in L(\text{EPCFN}) \).

**Proof.**

Let \( G_1 = (\Sigma_1, h_1, \omega_1, \Delta) \) be the ECFN system where
\[
\Sigma_1 = \Sigma \cup \hat{\Sigma} \cup \Sigma \cup \{F\}\cup \{a\mid a \in \Sigma\}, \hat{\Sigma} = \{\hat{a} \mid a \in \Sigma\}, \Sigma = \{a \mid a \in \Sigma\},
\]
\[
\omega_1 = \tilde{\omega}(\text{for a word } x, \tilde{x} \text{ results from } x \text{ by replacing each occurrence of a letter } a \text{ in } x \text{ by } \hat{a}; \text{ analogously one gets } \hat{x} \text{ and } \overline{x}),
\]
\[
h_1(\hat{a}) = \{a\} \text{ for } a \in \Sigma \setminus \Delta,
\]
\[
h_1(\hat{a}) = \{\hat{a}, a\} \text{ for } a \in \Delta,
\]
\[
h_1(\hat{a}) = \{\overline{a}\} \text{ for } a \in \Sigma \setminus \Delta,
\]
\[
h_1(\hat{a}) = \{\overline{a}, f(a)\} \text{ for } a \in \Delta,
\]
\[
h_1(\overline{x}) = \{x \mid x \in h(a)\} \text{ for } a \in \Sigma,
\]
\[
h_1(a) = h_1(F) = \{F\} \text{ for } a \in \Delta.
\]
Derivations in $G_1$ in which no symbols of $\Delta$ occur simulate derivations in $G$: if $x = y$ then the simulating derivation in $G_1$ is a "composition" of rounds $\bar{\Delta} \ast \bar{\Delta} \ast \bar{\Delta} \ast \bar{\Delta}$. By Lemma II.1,

$$L(G_1) = \{v_2 u | v_2, u \in \bar{\Delta}^* \text{ and, for some } v_1 \in \bar{\Delta}^*, u \in h_1(v_1) \text{ and } v_1 v_2 \in L(U_{OL}(G_1))\}.$$  

From the construction of $G_1$ it follows that in the above $v_1$ and $v_2$ must be such that $v_2 \in \Delta^*$ and $v_1 \in \bar{\Delta}^*$; i.e. $v_1 v_2 = \bar{x}_1 v_2$ with $x_1 v_2 \in L(G)$ and $\bar{x}_1 v_2$ produces $v_2 f(x_1)$. Consequently $L(G_1) = \{x_2 f(x_1) | x_2 x_1 \in L(G)\} = cyf L(G)$. Moreover if $G$ is propagating then so is $G_1$. Since $G$ can be assumed to be propagating, the theorem holds. $\square$

This yields the following closure result for $L(\text{ECFN})$.

**Theorem III.2.** $L(\text{ECFN})$ is closed under cyclic permutation.

**Proof.**

Let $K \in L(\text{ECFN})$. By Theorem II.1 there exists an EOL language $M$ such that $K \sim M$ (and so $\text{cyc } K = \text{cyc } M$). By Lemma III.1 (take $f$ to be the identity mapping) $\text{cyc } M \in L(\text{ECFN})$ and so $\text{cyc } K \in L(\text{ECFN})$. $\square$

As a matter of fact $f$-cyclic permutations provide our first characterization of $L(\text{ECFN})$ in terms of $L(\text{EOL})$.

**Theorem III.3.** Let $\Delta$ be an alphabet, $\bar{\Delta} = \{\bar{a} | a \in \Delta\}$ and $K \subseteq \Delta^*$. Then $K \in L(\text{ECFN})$ if and only if there exist an EOL language $M$ and a coding $f$ on $(\Delta \cup \bar{\Delta})^*$ such that $K = \Delta^* \cap \text{cyc}_f M$.

**Proof.**

The "if" part of the statement of the theorem follows from Lemma III.1 (and from the obvious observation that to get an intersection with $\Delta^*$ one changes the terminal alphabet of the system considered to $\Delta$).

To prove the "only if" part we proceed as follows. Let $G = (\Sigma, h, \omega, \Delta)$ be an ECFN system
and let \( K = L(G) \). Let \( M = \{ u, v_2 | u, v_2 \in \Delta^* \text{ and, for some } v_1 \in \Sigma^*, u \in h(v_1) \text{ and } v_1v_2 \in L(U_{OL}(G)) \} \), where for a word \( x \in \Delta^* \), \( \bar{x} \) is obtained by replacing every occurrence of every letter \( a \) in it by \( \overline{a} \). Clearly \( M \) can be obtained from \( L(U_{OL}(G)) \) by a gsm mapping, hence \( M \in L(EOL) \). Let \( f \) be the coding on \((\Delta U \overline{\Delta})^* \) defined by \( f(a) = \overline{a} \), and \( f(\overline{a}) = a \) for all \( a \in \Delta \). Then .
\[ \Delta^* \cap cyfM = \{ v_2u | u, v_2 \in \Delta^* \text{ and, for some } v_1 \in \Sigma^*, u \in h(v_1) \text{ and } v_1v_2 \in L(U_{OL}(G)) \} \]
and so by Lemma II.1, \( \Delta^* \cap cyfM = L(G) = K \). Hence the theorem holds. □

Theorem III.3 allows one to prove the following normal form theorem for ECFN systems.

**Theorem III.4.** \( L(ECFN) = L(EPCFN) \).

**Proof.**

Clearly \( L(EPCFN) \subseteq L(ECFN) \).

To prove that \( L(ECFN) \subseteq L(EPCFN) \) let \( K \in L(ECFN) \), \( K \subseteq \Delta^* \). By Theorem III.3, \( K = \Delta^* \cap cyfM \) where \( M \) is an EOL language and \( f \) is a coding. Hence, by Lemma III.1, \( cyfM \in L(EPCFN) \) and so obviously \( K = \Delta^* \cap cyfM \in L(EPCFN) \). □

We end this section be establishing the closure of \( L(ECFN) \) under gsm mappings.

**Theorem III.5.** \( L(ECFN) \) is closed under gsm mappings.

**Proof.**

Let \( G = (\Sigma, h, \omega, \Delta) \) be an ECFN system, let \( K = L(G) \), and let \( g \) be a gsm mapping, \( g : \Delta^* \rightarrow \Omega^* \). For words \( u_1, u_2 \in \Delta^* \) and \( v_1, v_2 \in \Omega^* \) we write \( \langle v_1, v_2 \rangle \in g(u_1, u_2) \) if and only if \( v_1v_2 \in g(u_1u_2) \) and moreover \( v_1 \) is the output produced by \( g \) during the processing of \( u_i \), \( i \in \{1,2\} \).

Consider the language \( M \subseteq (\Omega U \overline{\Omega})^* \) defined by

\[ M = \{ \overline{xy} | x, y \in \Omega^* \text{ and for some words } u, v_1, v_2 \in \Sigma^*, v_1v_2 \in L(U_{OL}(G)), v_2u \in \Delta^*, u \in h(v_1) \text{ and } \langle y, x \rangle \in g(v_2, u) \} \].
It is easy to see that there exists a gsm \( g_1 \) such that \( g_1(L(U_{OL}(G))) = M \): \( g_1 \) starts in a state \( q \) of \( g \) (chosen nondeterministically) on some \( v_1v_2 \in L(U_{OL}(G)) \), then it simulates \( g \) on a string \( u \in h(v_1) \) putting bars on the output letters until it arrives in a final state; at this moment \( g_1 \) starts a simulation of \( g \) on \( v_2 \) beginning in the initial state of \( g \); the whole simulation can be finished only when \( g \) arrives at \( q \). Thus \( M \in L(EDL) \).

By Lemma II.1, \( g(K) = \{yx | xy \in M \} \). Hence \( g(K) = \Omega^* \cap c_{y_0}fM \) where \( f \) is the coding on \( (\Omega \cup \overline{\Omega})^* \) defined by \( f(a) = \overline{a} \) and \( f(\overline{a}) = a \) for all \( a \in \Omega \).

Thus by Lemma III.1, \( g(K) \in L(ECFN) \). \( \square \)
IV. THE RELATIONSHIP OF $L(\text{ECFN})$ TO $L(\text{EOL})$ AND $L(\text{ETOL})$

The aim of this section is to establish a precise relationship between $L(\text{ECFN})$ on the one hand and $L(\text{EOL})$ and $L(\text{ETOL})$ on the other hand.

We start by strengthening Lemma II.2.

Theorem IV.1. $L(\text{EOL}) \not\subseteq L(\text{ECFN})$.

Proof.

By Lemma II.2, $L(\text{EOL}) \subseteq L(\text{ECFN})$.

It is well-known (see, e.g.,[14]) that $K = \{a^n b^m a^n \mid m \geq n \geq 1\} \not\subseteq L(\text{EOL})$.

That $K \in L(\text{ECFN})$ is seen as follows. Let $K_1 = \{b^m a^n s a^n \mid m \geq n \geq 1\}$; clearly $K_1$ is context free and so $K_1 \in L(\text{EOL})$. But $K = f([a, b]^* s \cap \omega s K_1)$ where $f$ is the homomorphism on $[a, b, s]^*$ defined by $f(a) = a$, $f(b) = b$ and $f(s) = \Lambda$. Hence by Lemma II.2, Theorem III.2 and Theorem III.5, $K \in L(\text{ECFN})$ and consequently $L(\text{ECFN}) \setminus L(\text{EOL}) \neq \emptyset$.

Thus the theorem holds. $\square$

Remark. It is instructive to notice that the language $K$ from the proof above is generated by the ECFN system $G = (\Sigma, h, \omega, \Delta)$ where

$\Sigma = \{A, B, A, \overline{B}, F, a, \overline{a}, \overline{a}, b, \overline{B}, 0\}$, $\Delta = \{a, b\}$, $\omega = AB\overline{a}$ and $h$ is defined by

$h(A) = \{A, A\overline{A}, \overline{a}\}$,
$h(B) = \{B\overline{B}, b\}$
$h(x) = \{x, x\}$ for $x \in \{a, b\}$,
$h(x) = \{x\}$ for $x \in \{a, b\}$,
$h(\overline{x}) = \{x\}$ for $x \in \{A, B\}$, and
$h(x) = \{F\}$ for $x \in \{a, b, F\}$. $\square$

The following result puts Theorem IV.1 in a better perspective.

Theorem IV.2. Let $\Delta$ be an alphabet, $\#\Delta = 1$ and let $K \subseteq \Delta^*$. Then $K \in L(\text{EOL})$ if and only if $K \in L(\text{ECFN})$. 
Proof.

Directly from Theorem II.1. \(\square\)

We provide now another characterization of \(L(\text{ECFN})\) in terms of \(L(\text{EOL})\). We need the following lemma first.

Lemma IV.1. For every language \(K \in L(\text{ECFN})\) there exist a language \(M \in L(\text{EOL})\) and a gsm mapping \(g\) such that \(K = g(cyc M)\).

Proof.

Let \(K = L(G)\) where \(G = (\Sigma, h, \omega, \Delta)\) is an ECFN system. Let \(\gamma \notin \Delta\) and let \(M = L(\text{U}_{\text{OL}}(G))\gamma \); clearly \(M \in L(\text{EOL})\). Let \(g\) be the gsm mapping that translates \(v_2 \gamma v_1\) into all \(v_2 u\) such that \(u \in h(v_1)\); moreover \(g\) accepts only if the output \(v_2 u \in \Delta^*\). Then Lemma II.1 implies that \(K = g(cyc M)\). \(\square\)

Theorem IV.3. \(L(\text{ECFN}) = \{g(cyc M) \mid M \in L(\text{EOL})\text{ and } g\text{ is a gsm mapping}\}\), moreover \(L(\text{ECFN})\) is the smallest class of languages containing \(L(\text{EOL})\) and closed under cyclic permutation and gsm mappings.

Proof.

This follows directly from Lemma IV.1, Lemma II.2, Theorem III.2 and Theorem III.5. \(\square\)

Remark. It is easy to see that using Theorem III.2 and Theorem III.5 one can strengthen Theorem III.2 to the closure of \(L(\text{ECFN})\) under \(f\)-cyclic permutations. Hence, by Theorem III.3, \(L(\text{ECFN})\) is the smallest class containing \(L(\text{EOL})\) and closed under \(f\)-cyclic permutations and intersections with \(\Delta^*\). Comparing this result with Theorem IV.3 one sees a trade-off between an arbitrary gsm mapping and cyclic permutation on the one hand and a trivial gsm mapping (\(\cap \Delta^*\)) and \(f\)-cyclic permutations on the other hand. \(\square\)

Based on Theorem IV.3 we also get the following additional positive closure property which we consider quite surprising.
Theorem IV.4. \( L(\text{ECFN}) \) is closed under mirror image.

Proof.

Let \( K \in L(\text{ECFN}) \). By Theorem IV.3, there exist an EOL language \( M \) and a gsm mapping \( g \) such that \( K = g(\text{eye } M) \). Obviously for an arbitrary language \( Z \) and for an arbitrary gsm mapping \( f \) we have \( \text{eye}(\text{mir } Z) = \text{mir}(\text{eye } Z) \) and \( \text{mir } f(Z) = f_1(\text{mir } Z) \) for some gsm mapping \( f_1 \) (simply, \( f_1 \) simulates \( f \) "backwards"). Consequently \( \text{mir } K = \text{mir}(g(\text{eye } M)) = g_1(\text{mir}(\text{eye } M)) = g_1(\text{eye}(\text{mir } M)) \) for some gsm mapping \( g_1 \). Since obviously \( L(\text{EOL}) \) is closed under mirror image, Theorem IV.3 implies that \( \text{mir } K \in L(\text{ECFN}) \).

Hence the theorem holds. \( \Box \)

The above result shows that if one defines extended context free normal systems to operate in the right-to-left mode (that is rules are of the form \( Px \to yP \)) then one obtains the same class of languages.

Finally we settle an open problem from [3].

Corollary IV.1. \( L(\text{EOL}) \) is not closed under cyclic permutation.

Proof.

It follows directly from Theorem IV.3, Theorem IV.1 and the fact that \( L(\text{EOL}) \) is closed under gsm mappings. \( \Box \)

\( L(\text{EOL}) \) is not closed under cyclic permutation, but \( L(\text{EOL}) \) is not an AFL (see, e.g., [14]). To put Corollary IV.1 in a proper perspective we provide now an example of a full AFL which is not closed under cyclic permutation (another example of this situation is given in [3]).

Remark. Consider the full AFL \( L(\text{STACK}) \) of stack languages ([5]). Clearly \( K_1 = \{ b^n c^n a^n \mid n \geq 1 \} \) is a stack language, however according to [12], \( K_2 = \{ a^n b^n c^n \mid n \geq 1 \} \) is not a stack language. Since \( K_2 = a^* b^* c^* \cap \text{cyc } K_1 \), \( L(\text{STACK}) \) is an example of a full AFL that is not closed under cyclic permutation. \( \Box \)
We move now to consider the relationship between \( L(\text{ECFN}) \) and \( L(\text{ETOL}) \). The following result is from [9], however we provide a different proof for it.

Lemma IV.2. ([9]). \( L(\text{ECFN}) \subseteq L(\text{ETOL}) \).

Proof.

This follows from Theorem IV.3, Lemma I.1 and the well known facts (see, e.g., [14]) that \( L(\text{EOL}) \subseteq L(\text{ETOL}) \) and \( L(\text{ETOL}) \) is closed under gsm mappings. \( \Box \)

Our next result strengthens Lemma IV.2 and answers a question from [9].

Theorem IV.5. \( L(\text{ECFN}) \nsubseteq L(\text{ETOL}) \).

Proof.

By Lemma IV.2 \( L(\text{ECFN}) \subseteq L(\text{ETOL}) \). It is well known (see [8]) that \( L(\text{ETOL}) \setminus L(\text{EOL}) \) contains languages over a one letter alphabet. Hence by Theorem IV.2, \( L(\text{ETOL}) \setminus L(\text{ECFN}) \neq \emptyset \) and the theorem holds. \( \Box \)

In the next section we will see further examples of languages in \( L(\text{ETOL}) \setminus L(\text{ECFN}) \).
V. NEGATIVE CLOSURE PROPERTIES.

In order to have a more complete picture of $L(\text{ECFN})$ we move now to investigate several nonclosure properties of $L(\text{ECFN})$.

Theorem V.1. $L(\text{ECFN})$ is neither closed under inverse homomorphisms nor is it closed under regular substitutions.

Proof.

Let $K = \{ x \in \{a,b\}^* |$ the number of occurrences of $a$ in $x$ equals $2^n$ for some $n \geq 0 \}$. It is well known (see [7]) that $K \notin L(\text{EOL})$.

Assume that $K \in L(\text{ECFN})$. Then by Theorem II.1 there exists an EOL language $M$ such that $K \sim M$.

Let $f$ be the finite substitution on $\{a,b\}^*$ defined by $f(a) = \{a\}$ and $f(b) = \{b, A\}$. It is easy to see that $K = b^* f(M) b^*$. Since obviously $L(\text{EOL})$ is closed under finite substitutions and under the operation of catenating $b^*$ in front of and behind any string of a language, $K \in L(\text{EOL})$; a contradiction. Thus $K \notin L(\text{ECFN})$.

Since obviously $K_0 = \{ a^{2^n} | n \geq 0 \}$ is an EOL language and hence (Lemma II.2) an ECFN language and since $K$ can be easily obtained from $K_0$ by both an inverse homomorphism and a regular substitution the theorem holds. $\square$

Since it is well known that $L(\text{ETOL})$ is closed both under inverse homomorphisms and under regular substitutions, the above result together with Lemma IV.2. yields an alternative proof of Theorem IV.5.

Next we recall a definition of an operation quite useful in investigating various classes of languages (see [16]).

Definition. Let $\Delta$ be an alphabet and let $\not\in \Delta$. The copy operator (on $\Delta^*$) is the mapping $c_2 : \Delta^* \rightarrow (\Delta \cup \not\in)^*$ defined by $c_2(x) = x \not\in x$ for $x \in \Delta^*$. For a language $K \subseteq \Delta^*$, $c_2(K) = \{ x \not\in x | x \in K \}$. $\square$

Theorem V.2. $L(\text{ECFN})$ is not closed under copying.
Proof.

Assume to the contrary that $L(ECFN)$ is closed under copying. Let $K \in L(EOL)$, $K \subseteq \Delta^*$. 

Then, by Lemma II.2 and Theorem III.5 it easily follows (apply copying twice) that $K_1 = \{x \not\in \varepsilon x \not\in \varepsilon | x \in K\} \in L(ECFN)$. By Theorem II.1 there exists an EOL language $M$ such that $K_1 \sim M$. Clearly all words in $M$ are of the form $y \not\in \varepsilon x \not\in \varepsilon z$ where $x \in K$, $y$, $z \in \Delta^*$ and moreover for every $x \in K$ a word of this form is in $M$. Hence there exists a gsm mapping $g$ such that $g(M) = c_2(K)$. Since $L(EOL)$ is closed under gsm mappings, $c_2(K) \in L(EOL)$. This implies that $L(EOL)$ is closed under copying, which contradicts [16].

Thus we conclude that $L(ECFN)$ is not closed under copying. $\Box$

Before we prove our next nonclosure result we need the following result bridging in a special way $L(ECFN)$ and $L(EOL)$, and so interesting on its own.

Lemma V.1. Let $\Delta$ be an alphabet, $\varepsilon \not\in \Delta$ and let $K_1, K_2$ be languages over $\Delta$. If $K_1 \not\subseteq K_2 \in L(ECFN)$ then either $K_1 \in L(EOL)$ or $K_2 \in L(EOL)$.

Proof.

In this proof we apply the usual translational technique of which Greibach's "syntactic lemma" (see [6]) is a well known example.

Assume that $K_1 \not\subseteq K_2 \in L(ECFN)$ and let $\varepsilon \not\in (\Delta \cup \{\varepsilon\})$.

Then by Theorem III.5, $K_1 \not\subseteq K_2 \varepsilon \in L(ECFN)$. Let $G = (\Sigma, h, \omega, \Delta)$ be an EFCN system such that $L(G) = K_1 \not\subseteq K_2 \varepsilon$. By Theorem II.1 there exists an EOL language $M$ such that $L(G) \sim M$.

Let $g_1$ be the gsm mapping that translates every word of the form $z\varepsilon y\varepsilon x$ with $x, y, z \in \Delta^*$ into $y$ (and $g_1$ rejects words of any other form).

Similarly let $g_2$ be the gsm mapping that translates every word of the form $z\varepsilon y\varepsilon x$ with $x, y, z \in \Delta^*$ into $y$ (and $g_2$ rejects words of any other form). Since $L(G) \sim M$, $g_1(M) \subseteq K_1$ and $g_2(M) \subseteq K_2$.

We consider separately two cases
Case 1. For every \( y \in K_1 \) there exist \( x, z \in \Delta^* \) such that \( z \varepsilon y \varepsilon x \in M \) and \( xz \in K_2 \).

Then clearly \( K_1 \subseteq g_1(M) \) and consequently \( K_1 = g_1(M) \).

Case 2. For every \( y \in K_2 \) there exist \( x, z \in \Delta^* \) such that \( z \varepsilon y \varepsilon x \in M \) and \( xz \in K_1 \).

Then clearly \( K_2 \subseteq g_2(M) \) and consequently \( K_2 = g_2(M) \).

Since \( L(EOL) \) is closed under gsm mappings, to complete the proof it suffices to demonstrate that cases 1 and 2 together exhaust all possibilities. To this aim assume that case 1 does not hold. Thus there exists a word \( y_1 \in K_1 \) such that for all \( y_2 \in K_2 \) and all \( x, z \in \Delta^* \) such that \( xz = y_2 \), \( z \varepsilon y_1 \varepsilon x \not\in M \). Hence for this particular \( y_1 \in K_1 \) and for any \( y_2 \in K_2 \) if \( u \in M \) is a cyclic conjugate of \( y_1 \varepsilon y_2 \varepsilon \in L(G) \) then \( u = z_1 \varepsilon y_2 \varepsilon x_1 \) for some \( x_1, z_1 \in \Delta^* \) such that \( x_1 z_1 = y_1 \). Consequently case 2 holds.

Thus the lemma holds. \( \Box \)

Since it is well known (see, e.g., [78]) that \( L(EOL) \) is closed under catenation, Lemma V.1. says that \( L(EOL) \) is the largest subclass of \( L(ECFN) \) closed under marked catenation.

Theorem V.3. \( L(ECFN) \) is neither closed under catenation nor is it closed under Kleene star.

Proof.

Let \( K \notin L(ECFN) \setminus L(EOL) \), by Theorem IV.1 such a \( K \) exists. By Theorem III.5, \( K \notin L(ECFN) \) where \( K \subseteq \Delta^* \) and \( \not\in \Delta \). If we assume now that \( L(ECFN) \) is closed under catenation then \( K \notin K \notin L(ECFN) \) and so by Theorem III.5, \( K \notin K \in L(ECFN) \). But this contradicts Lemma V.1 and consequently \( L(ECFN) \) is not closed under catenation.

If we assume that \( L(ECFN) \) is closed under Kleene star, then by Theorem III.5, \( (K \notin)^* \in L(ECFN) \) and so, again by Theorem III.5, \( K \notin K \in L(ECFN) \) which contradicts Lemma V.1. Thus \( L(ECFN) \) is not closed under Kleene star. \( \Box \)
ACKNOWLEDGEMENTS

The authors are indebted to M. Kudlek for introducing them to the topic of ECFN systems. The first and the third author gratefully acknowledge the support of NSF grant MCS 79-03838.
