Appendix I: Applets for Interactive Testing
from Data Structures & Other Objects Using Java

It's useful to have a small interactive test program to help you test class methods. Such a program can be written as a Java applet, which is a Java program written in a special format to have a graphical user interface. The graphical user interface is also called a GUI (pronounced "gooey"), and it allows a user to interact with a program by clicking the mouse, typing information into boxes, and performing other familiar actions. With a Java applet, GUls are easy to create, even if you've never run into such goo before.

This appendix shows one simple pattern for developing such applets. To illustrate the pattern, we'll implement an applet that lets you test three of the bag's methods (size, add, and countOccurrences from Chapter 3). When the bag applet starts, a GUI is created, similar to the drawing in Figure I.1(a).

By the way, the word “applet” means a particular kind of Java program, so you might show Figure I.1 to your boss and say, “My applet created this nice GUI.” But you can also use the word “applet” to talk about the GUI itself, such as “The applet in Figure I.1(a) has three buttons in its middle section.” And, in fact, there are three buttons in that applet—the rectangles labeled size(), add(), and countOccurrences().

The applet in Figure I.1 is intended to be used by the programmer who wrote the IntArrayBag class, to check interactively that the class is working correctly. When the applet starts, two sentences appear at the top: “This test program has created a bag. Press buttons to activate the bag's methods.” Above these sentences are some extra items, shown here:

The display above our sentences is created automatically by the applet display mechanism. The exact form of this display varies from one system to another, but the dark bar across the top generally contains controls such as the \( \times \) in the top-right corner. Clicking on that \( \times \) with the mouse closes the applet on this particular system.

A series of buttons appears in the middle part of the applet, like this:
(a) When the applet first opens, the applet has the components shown here.

(b) The user interacts with the applet by typing information and clicking on the buttons with the mouse. In this example, the user has typed 42 into the add text field and then clicked the add button. The applet responds with the message “42 has been added to the bag,” written in the text area at the bottom of the applet.
To test the bag, the user clicks on the various buttons. For example, the user can click on \texttt{size()}, and a new message will appear in the large text area at the bottom of the applet. The message will display the current size of the bag, as obtained by activating the \texttt{size()} method. If you click on this button right at the start, you’ll get the message “The bag’s size is 0.”

The user can also activate \texttt{add} or \texttt{countOccurrences}, but these methods each need an argument. For example, to add the number 42 to the bag, the user types the number 42 in the white box next to the \texttt{add} button and then clicks \texttt{add()}. The result of adding 42 is shown in Figure I.1(b). After elements have been added, the user can test \texttt{countOccurrences}. For example, to count the occurrences of the number 10, the user types 10 in the box by the \texttt{countOccurrences} button and then clicks \texttt{countOccurrences()}. The applet activates \texttt{countOccurrences(10)} and prints the method’s return value in the large text area at the bottom.

\section*{Six Parts of a Simple Interactive Applet}

Figure I.2 on page 8 shows an outline for the Java code of the applet that tests the \texttt{IntArrayBag}. The same outline can be used for an applet that interactively tests any class. The code has six parts, which we’ll discuss now.

1. \textbf{Import statements.} As with any Java program, we begin with a collection of import statements to tell the compiler about the other classes that we’ll be using. In the case of the bag applet, we import the \texttt{IntArrayBag} class (using the statement \texttt{import edu.colorado.collections.IntArrayBag;}). Most applets also have these three import statements:

   \begin{verbatim}
   import java.applet.Applet;
   import java.awt.*;
   import java.awt.event.*;
   \end{verbatim}

   The first import statement provides a class called \texttt{Applet}, which we’ll use in a moment. The other two import statements provide items from the \texttt{abstract windowing toolkit} (the “AWT”), which is a collection of classes for drawing buttons and other GUI items.

2. \textbf{The class definition.} After the import statements, we define a class, much like any other Java class. This class definition begins with the line:

   \begin{verbatim}
   public class BagApplet extends Applet
   \end{verbatim}

   The definition continues down to the last closing bracket of the file. The class for the bag applet is called \texttt{BagApplet}, which is certainly a good name, but what does “extends \texttt{Applet}” mean? It means that the \texttt{BagApplet} class will not be written entirely by us. Instead, the class begins by already having all the non-private methods of another class called \texttt{Applet}. We imported the \texttt{Applet} class from \texttt{java.applet.Applet}, and it is provided as part of the Java language so that a class such as \texttt{BagApplet} does not have to start from scratch. The act of obtaining methods from another class is called \texttt{inheritance}. The class that provides these methods (such as the \texttt{Applet} class) is called the \texttt{superclass}, and the new class (such as \texttt{BagApplet}) is called the \texttt{extended class}. Chapter 13 studies inheritance in detail, but for now, all you need to know is that the \texttt{BagApplet} obtains a
bunch of methods from the Applet class without having to do anything more than specify "extends Applet."

At the top of the class, we define an IntArrayBag instance variable:

```java
IntArrayBag b = new IntArrayBag();
```

This bag, `b`, will be manipulated when the user clicks on the applet’s buttons. In general, an interactive test applet will have one or more objects declared here, and these objects are manipulated by clicking the applet’s buttons.

### 3. Declarations of the applet’s components.

An applet’s components are the buttons and other items that are displayed when the applet runs. These components are declared as instance variables of the class. Our bag applet has several kinds of components: buttons (such as `add()`), text fields (which are the white rectangles next to some of the buttons), and a text area (which is the large rectangle in the bottom third of the applet). In all, there are six important components in the bag applet, represented by these six instance variables:

- `Button sizeButton` - new Button("size( )");
- `Button addButton` - new Button("add( )");
- `TextField elementText` - new TextField(10);
- `Button countOccurrencesButton` - new Button("countOccurrences( )");
- `TextField targetText` - new TextField(10);
- `TextArea feedback` - new TextArea(7, 60);

All the instance variables are declared near the top of the class definition before any of the method definitions. They cannot have the usual private access, because they’ll be accessed from other classes that we’ll see shortly. But before that, let’s look at the three kinds of components: button, text field, and text area.

A **button** is a grey rectangle with a label. When a button is created, the constructor is given a string that is printed in the middle of the button. For example, this declaration creates a button called `sizeButton`, and the label on the button is the string "size( )":

```java
Button sizeButton = new Button("size( )");
```

The bag applet has three buttons: `sizeButton`, `addButton`, and `countOccurrencesButton`.

A **text field** is a white rectangle that can display one line of text. A text field is set up so that the program’s user can click on the field and type information, and the applet can then read that information. Our applet has two text fields, one next to the `add` button and one next to the `countOccurrences` button. The TextField class has a constructor with one argument—an integer that specifies approximately how many characters can fit in the text field. For example, one of our text fields is declared as follows:

```java
TextField elementText = new TextField(10);
```

The `elementText` text field can hold about 10 characters. The user can actually type beyond 10 characters, but only 10 characters of a long string will be displayed. We plan to display `elementText` right beside the `add` button, like this:
To test the add method, the user will type a number in the text field and click on the add button.

A text area is like a text field with more than one line. Its constructor has two arguments that specify the number of rows and columns of text to display. Our bag applet has one text area:

    TextArea feedback = new TextArea(7, 60);

This large text area appears at the bottom of the applet. The intention is to use the text area to display messages to the user.

The declarations we have seen create the three kinds of components: Button, TextField, and TextArea. All three classes are part of the java.awt package that is imported by our applet. When we declare a button (or other component) and create it with the constructor, it does not immediately appear in the GUI. How do the objects get placed in the GUI? Also, how does the applet know what to do when the user clicks on a button or takes some other action? The answers to these two questions lie in a special applet method called init, which we'll discuss next.

4. The init method. A Java application program has a special static method called main, but a Java applet does not have main. Instead, an applet has a special nonstatic method called init. When an applet runs, the runtime system creates an object of the applet class and activates init() for that object. There are several other applet methods that the runtime system also activates at various times, but an interactive test program needs only init.

Our init method carries out four kinds of actions:

A. The add method. We can add one of the interactive components to the GUI. This is done with an applet method called add. The method has one argument, which is the component being added to the GUI. For example, one of our buttons is sizeButton, so we can write the statement:

    add(sizeButton);

As components are added, the GUI fills up from left to right. If there is no room for a component on the current line, then the GUI moves down and starts a new row of components. Later you can learn more sophisticated ways of laying out the components of a GUI, but the simple left-to-right method used by an applet is a good starting point.

B. Displaying messages. We can display messages in the GUI. Each message is a fixed string that provides some information to the user. Each of these messages is a Label object (from the package java.awt). To create and display a message, we activate add with a newly created Label as the argument. For example:

    add(new Label("This test program has created a bag"));

The Label constructor has one argument, which is the string that you want to display. The add method will put the message in the next available spot of the GUI.

C. New lines and horizontal lines. If our applet class has other methods (besides init), then we can activate these other methods. For example, we plan to have two other methods in the IntArrayBag class:

    void addNewLine( );
    void addHorizontalLine(Color c);

The addNewLine method forces the GUI to start a new line, even when there's room for more components on the current line. The second method, addHorizontalLine, draws a horizon-
Appendix I / from Data Structures & Other Objects Using Java

tal line in the specified color. We'll have to define these two methods as part of BagApplet.java, but they won't be difficult. (The data type Color is part of java.lang. It includes Color.blue and 12 other colors, plus the ability to define your own colors.)

D. Activate methods of the components. The buttons and other components have methods that can be activated. For example, one of the methods of a TextArea is called append. The method has one argument, which is a string, and this string is appended to the end of what's already in the text field. One of the statements in our init method will activate append:

```java
feedback.append("I am ready for your first action.\n");
```

This causes the message “I am ready for your first action.” to be written in the feedback text field (with a newline character \n at the end of the message).

The most important method for buttons involves a new kind of object called an action listener. An action listener is an object that an applet programmer creates to describe the action that should be taken when certain events occur. Our bag applet will have a different kind of action listener for each of the three buttons:

<table>
<thead>
<tr>
<th>Kind of Action Listener</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>SizeListener</td>
<td>Describes the actions to be taken when sizeButton is clicked.</td>
</tr>
<tr>
<td>AddListener</td>
<td>Describes the actions to be taken when addButton is clicked.</td>
</tr>
<tr>
<td>CountOccurrencesListener</td>
<td>Describes the actions to be taken when countOccurrencesButton is clicked.</td>
</tr>
</tbody>
</table>

Each kind of action listener is actually a new class that we'll define in a moment. But the only thing you need to know for the init method is how to connect an action listener to a Button. The solution is to activate a method called addActionListener for each Button. For example, to connect sizeButton to its action listener, we place this statement in the init method:

```java
sizeButton.addActionListener(new SizeListener());
```

Notice that addActionListener is a method of the Button class, and its one argument is a new SizeListener object. Of course, we still need to implement the SizeListener class, as well as the other two action listener classes. But first let's summarize all the pieces that are part of the init method for the BagApplet. Within init, we expect to activate these methods to carry out our work:

- add—An Applet method to add the buttons and other components to the display
- addNewLine and addHorizontalLine—Two methods that we will write for the BagApplet
- feedback.append—A method of feedback (a TextArea object) to place the message “I am ready for your first action” in feedback
• addActionListener—A method that will be called once for each of the three buttons

The complete init implementation is shown in Figure I.2. We've used just one method that we haven't yet mentioned. That one method (setEditable) is summarized in Figure I.3 on page 9, along with the other applet-oriented methods that we have used or plan to use.

5. Implementations of the action listeners. The next step of the applet implementation is to design and implement three action listener classes—one for each of our three buttons. The purpose of an action listener is to describe the actions that are carried out when a button is pushed.

Here's the Java syntax for defining an action listener class; the blank line is filled in with your choice of a name for the action listener class.

```java
class __________ implements ActionListener
{
    void actionPerformed(ActionEvent event)
    {
        ...
    }
}
```

The phrase “implements ActionListener” informs the Java compiler that the class will have a certain method that is specified in the ActionListener interface that is part of java.awt.*. The method, called actionPerformed, is shown with “...” to indicate its body. The actionPerformed method will be executed when an action occurs in the action listener's component, such as clicking a button. For example, here is the complete definition of the action listener that handles the clicking of the button of our test applet:

```java
class SizeListener implements ActionListener
{
    void actionPerformed(ActionEvent event)
    {
        feedback.append("The bag has size " + b.size() + "\n");
    }
}
```

This declares a class called SizeListener, which includes its own actionPerformed method. For most classes, the class definition would go in a separate file called SizeListener.java. But a separate file is undesirable here because the actionPerformed method needs access to two instance variables: the bag b and the text area feedback. The necessary access can be provided by placing the entire SizeListener definition within the BagApplet. This is an example of an inner class, where the definition of one class is placed inside of another. An inner class has two key properties:

• The larger class that encloses an inner class may use the inner class, but the inner class may not be used elsewhere.

• The inner class may access non-private instance variables and methods of the larger class. Some Java implementations also permit an inner class to access private instance variables of the larger class. But other implementations forbid private access from an inner class. (Java implementations that are built into web browsers are particularly apt to forbid the private access.)
Implementation

```java
public void init()
{
    // Some messages for the top of the applet:
    add(new Label("This test program has created a bag.");
    add(new Label("Press buttons to activate the bag's methods.");
    addHorizontalLine(Color.blue);

    // The Button for testing the size method:
    add(sizeButton);
    addNewLine();

    // The Button and TextField for testing the add method:
    add(addButton);
    add(elementText);
    addNewLine();

    // The Button and TextField for testing the countOccurrences method:
    add(countOccurrencesButton);
    add(targetText);
    addNewLine();

    // A TextArea at the bottom to write messages:
    addHorizontalLine(Color.blue);
    addNewLine();
    feedback.setEditable(false);
    feedback.append("I am ready for your first action.
");
    add(feedback);

    // Tell the Buttons what they should do when they are clicked:
    sizeButton.addActionListener(new SizeListener());
    addButton.addActionListener(new AddListener());
    countOccurrencesButton.addActionListener(new CountOccurrencesListener());
}
```
## FIGURE 1.3  Guide to Building an Applet for Interactive Testing

<table>
<thead>
<tr>
<th>Methods to Call from an Applet or from a Class That Extends an Applet</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>add(component)</strong></td>
</tr>
<tr>
<td><strong>addNewLine()</strong></td>
</tr>
<tr>
<td><strong>addHorizontalLine(Color c)</strong></td>
</tr>
</tbody>
</table>

### Constructors for Three Useful Applet Components

<table>
<thead>
<tr>
<th>Constructor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Button(String label)</strong></td>
<td>Creates a button with a given label.</td>
</tr>
<tr>
<td><strong>TextField(int size)</strong></td>
<td>Creates a white box where the user can type information. The size is the number of characters.</td>
</tr>
<tr>
<td><strong>TextArea(int rows, int columns)</strong></td>
<td>Creates a box with the given number of rows and columns, often used for displaying information to the user.</td>
</tr>
</tbody>
</table>

### Six Useful Methods for a Component

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>b.setActionListener</strong></td>
<td>We use b.setActionListener for a Button b. The ActionListener, act, describes the actions to take when the Button b is pressed. See page 7 for information on how to create an ActionListener.</td>
</tr>
<tr>
<td><strong>t.append(String message)</strong></td>
<td>We use t.append for a TextArea t. The specified message is added to the end of the TextArea.</td>
</tr>
<tr>
<td><strong>t.getText()</strong></td>
<td>We use t.getText for a TextField t. The method returns a copy of the String that the user has typed in the field.</td>
</tr>
<tr>
<td><strong>t.setEditable(boolean editable)</strong></td>
<td>The component t can be either a TextArea or a TextField. The boolean parameter tells whether you want the user to be able to type text into the component.</td>
</tr>
<tr>
<td><strong>t.requestFocus()</strong></td>
<td>We use these methods with a TextField. The requestFocus method causes the mouse to go to the field, and selectAll causes all text to be highlighted.</td>
</tr>
<tr>
<td><strong>t.selectAll()</strong></td>
<td></td>
</tr>
<tr>
<td><strong>c.setSize(int width, int height)</strong></td>
<td>This method may be used with any component c. The component's width and height are set to the given values in pixels.</td>
</tr>
</tbody>
</table>
So, by making `SizeListener` an inner class, the `actionPerformed` method can activate `feedback.append` to print a message in the `feedback` component of the applet. The message itself includes an activation of `b.size()`, so an entire message is something like “The bag has size 42.”

The `actionPerformed` Method

The `SizeListener` class is an inner class, declared within `BagApplet`. Therefore, its `actionPerformed` method has access to the instance variables of the `BagApplet`.

By the way, the `actionPerformed` method has a parameter called `event`. For more complex actions, the `event` can provide more information about exactly which kind of action triggered the `actionPerformed` method.

Once an action listener is created, it must be registered with its particular button. The registration is made in the `init` method. Our applet had these three statements to register the three `ActionListener` objects:

```java
sizeButton.addActionListener(new SizeListener());
addButton.addActionListener(new AddListener());
countOccurrencesButton.addActionListener(new CountOccurrencesListener());
```

For example, the first of these statements creates a new `SizeListener` and registers it with the button `sizeButton`.

Let’s look at the second action listener class for our applet: `AddListener`. This action listener handles the actions of `addButton`, which is shown here along with the `TextField` that’s right beside it in the applet:

What actions should occur when the user clicks the `addButton`? The text is read from the `TextField`. This text is a `String`, such as “42”, but it can be converted to its value as an integer by using the Java method `Integer.parseInt`. The method `Integer.parseInt` has one argument (a `String` that contains an integer value), and the return value is the `int` value of the `String`. Once we know the value of the integer provided by the user, we can add it to the bag `b` and print an appropriate message. Here’s one implementation of these steps:
The `actionPerformed` method defined here uses three of the applet's instance variables: (1) `elementText`, which is the `TextField` where the user typed a number; (2) the `bag b`, where the new element is added; and (3) the `TextArea feedback`, where a message is printed providing feedback to the user.

The method works fine, though a problem arises if the user forgets to type a number in the `TextField` before clicking the button. In this case, a `NumberFormatException` will occur when `Integer.parseInt` tries to convert the user's string to an integer.

The best solution to this problem is to "catch" the exception when it occurs rather than allowing the exception to stop the applet. The syntax for catching a `NumberFormatException` looks like this:

```java
try {
    ...code that might throw a NumberFormatException...
}
catch (NumberFormatException e) {
    ...code to execute if the NumberFormatException happens...
}
```

The words `try` and `catch` are Java keywords for handling exceptions. The full power of `try` and `catch` are described in Appendix C. For our purposes, we'll follow the preceding pattern to write a better version of `AddListener`, show as part of Figure I.4 on page 14. In that implementation, `NumberFormatException` might occur, in which case the code in the `catch`-block is executed. This code prints a message in the feedback area of the applet and then activates two methods for `elementText` (which is the `TextField` where the user was supposed to type a number):

```java
    elementText.requestFocus();
    elementText.selectAll();
```

The `requestFocus` method causes the mouse cursor to jump into the `TextField`, and the `selectAll` method causes any text in the field to be highlighted. So now, if the user forgets to type a number, the applet will print a nice error message and provide a second chance.

Our applet needs one more action listener for the `countOccurrences` button. That implementation is part of Figure I.4 on page 14.
6. Implementations of other methods. Our applet has two other methods that we’ve mentioned: (1) \texttt{addHorizontalLine}, which draws a horizontal line in a specified color; and (2) \texttt{addNewLine}, which causes a new line to start in the GUI, even when there’s room for more components on the current line.

Our \texttt{addHorizontalLine} doesn’t really draw a line. Instead, it adds a component called a \texttt{Canvas} to the applet. A \texttt{Canvas} is another applet component, like a \texttt{Button}, primarily used for drawing graphical images. The size of the \texttt{Canvas} can be set in \texttt{pixels}, which are the individual dots on a computer screen. Today’s typical screens have about 100 pixels per inch, so a \texttt{Canvas} that is only one pixel high looks like a horizontal line. Our implementation is also part of Figure 1.4. Notice that in the implementation, the \texttt{Canvas} is 10,000 pixels wide, which is wide enough to span even the largest applet—at least on today’s computer screens.

Our last method, \texttt{addNewLine}, works by calling \texttt{addHorizontalLine} with the color set to the background color of the applet. In effect, we are drawing a horizontal line, but it is invisible because it’s the same color as the applet’s background.

The implementation of \texttt{addNewLine} is given in Figure 1.4 as part of the complete applet. Look through the implementation with an eye toward how it can be expanded to test all of the bag’s methods or to test a different class, such as the \texttt{DoubleArraySeq} class.

How to Compile and Run an Applet

An applet can be compiled just like any other Java program. For example, using the Java Development Kit, we can compile \texttt{BagApplet.java} with the command line:

```
javac BagApplet.java
```

You may have some other way of compiling Java programs in your development environment, but the result will be the same. The act of compiling produces the file \texttt{BagApplet.class}. The compilation will probably produce three other files with names such as \texttt{BagApplet$SizeListener.class}. These are the compiled versions of the inner classes.

Applets were actually created to run as part of a page that you view over the Internet with a web browser. These pages are called \texttt{html pages}, which stands for “hypertext markup language.” So, to run the \texttt{BagApplet}, we need a small html file. The file, called \texttt{BagApplet.html}, should be created by you in the same directory as \texttt{BagApplet.class}, and it should contain the two lines of html code shown here:

```
<applet code="BagApplet.class" width=480 height=340>
</applet>
```
The first line, containing `<applet...>`, tells the web browser that you are going to start an applet. Usually, you will have at least three pieces of information about the applet:

<table>
<thead>
<tr>
<th>code</th>
<th>Tells the browser where to find the compiled class.</th>
</tr>
</thead>
<tbody>
<tr>
<td>width - 480</td>
<td>Sets the applet’s size in pixels. Today’s typical screens have about 100 pixels per inch, so a size of 480 x 340 is about 4.8 inches by 3.4 inches.</td>
</tr>
<tr>
<td>height - 340</td>
<td></td>
</tr>
</tbody>
</table>

Many Java development environments have a feature to automatically create a small html file such as this.

Once the html file is in place, you can run the applet in one of two ways. One approach is to run an `appletviewer`, which is a tool that reads an html file and runs any applets that it finds. The Java Development Kit has an appletviewer that is executed from the command line. For example, to run the JDK appletviewer, you change to the directory that contains `BagApplet.html` and type the command:

```
appletviewer BagApplet.html
```

This command runs the applet, resulting in the display shown in Figure I.1 on page 791.

The applet can also be displayed by putting it in a location that's available to your web browser. My latest information about this approach is available at [http://www.cs.colorado.edu/~main/java.html](http://www.cs.colorado.edu/~main/java.html).

**Beyond the init Method**

Our test applet needed to define only the `init` method. More complex applets can also be created, involving graphical images plus interaction. Graphical applets will generally provide other methods called `start`, `paint`, `update`, `stop`, and `destroy`. A good resource is *Graphic Java, Mastering the AWT* by David M. Geary.
Java Applet Implementation

// File: BagApplet.java
// This applet is a small example to illustrate how to write an interactive applet that
// tests the methods of another class. This first version tests three of the IntArrayBag
// methods.

import edu.colorado.collections.IntArrayBag;
import java.applet.Applet;
import java.awt.*;  // Imports Button, Canvas, TextArea, TextField
import java.awt.event.*;  // Imports ActionEvent, ActionListener

public class BagApplet extends Applet
{
    // An IntArrayBag for this applet to manipulate:
    IntArrayBag b = new IntArrayBag();

    // These are the interactive components that will appear in the applet.
    // We declare one Button for each IntArrayBag method that we want to be able to
    // test. If the method has an argument, then there is also a TextField
    // where the user can enter the value of the argument.
    // At the bottom, there is a TextArea to write messages.
    Button sizeButton = new Button("Size()");  
    Button addButton = new Button("Add()");  
    TextField elementText = new TextField(10);  
    Button countOccurrencesButton = new Button("countOccurrences()");  
    TextField targetText = new TextField(10);  
    TextArea feedback = new TextArea(7,60);

    (continued)
(FIGURE I.4 continued)

```java
public void init()
{
    // See the implementation in Figure I.2 on page 8.
}

class SizeListener implements ActionListener
{
    public void actionPerformed(ActionEvent event)
    {
        feedback.append("The bag has size " + b.size() + ".\n");
    }
}

class AddListener implements ActionListener
{
    public void actionPerformed(ActionEvent event)
    {
        try
        {
            String userInput = elementText.getText();
            int element = Integer.parseInt(userInput);
            b.add(element);
            feedback.append(element + " has been added to the bag.\n");
        }
        catch (NumberFormatException e)
        {
            feedback.append("Type an integer before clicking button.\n");
            elementText.requestFocus();
            elementText.selectAll();
        }
    }
}
```

(continued)
class CountOccurrencesListener implements ActionListener
{
    public void actionPerformed(ActionEvent event)
    {
        try
        {
            String userInput = targetText.getText();
            int target = Integer.parseInt(userInput);
            feedback.append(target + " occurs ");
            feedback.append(b.countOccurrences(target) + "times.\n");
        }
